Recent advances in robotics and artificial intelligence (AI) are enabling the development of a wide range of systems with unique characteristics designed for varying real-world applications. These include robots that can engage in activities traditionally only completed by humans, such as sketching, painting and even hand-writing documents.

These robots could have interesting applications in both professional and creative contexts, as they could help to automate the creation of artistic renderings, legal papers, letters and other documents in real time. Most [handwriting robotic systems](#) to date have considerable limitations, such as high production costs (around \$150) and a large size.

Two researchers affiliated with the global student non-profit organization [App-In Club](#) recently developed a new cost-effective robotic handwriting system that could be more affordable for individual consumers, schools, universities and small businesses. This system, introduced in a [paper](#) on the *arXiv* preprint server, integrates a Raspberry Pi Pico microcontroller and other components that can be produced via 3D printing.

"This paper introduces a cost-effective robotic handwriting system designed to replicate human-like handwriting with high precision," Tianyi Huang and Richard Xiong wrote. "Combining a Raspberry Pi Pico microcontroller, 3D-printed components, and a machine learning-based handwriting generation model implemented via TensorFlow, the system converts user-supplied text into realistic stroke trajectories."

Compared to previously introduced robotic handwriting systems, the system designed and fabricated by these researchers is cheaper and more versatile, as it relies on lightweight plastic-based components produced via 3D printing instead of conventional metal components. Moreover, the researchers integrated the 3D-printed components using simpler

mechanical solutions, for instance, replacing the timing belts used in previous systems with lead screws.

This new system is also energy-efficient and can be easily customized to create different types of handwritten documents. The researchers also combined it with a machine learning-based model for handwriting generation, which they implemented via the open-source JavaScript library TensorFlow.js.

Huang and Xiong evaluated their system in a series of tests, where it was used to write various lines of text generated by its underlying machine-learning handwriting model. The written text created by the robotic system was then compared to the originals, overlaying them with printed versions of the machine-generated lines.

"By leveraging lightweight 3D-printed materials and efficient mechanical designs, the system achieves a total hardware cost of approximately \$56, significantly undercutting commercial alternatives," wrote the authors. "Experimental evaluations demonstrate handwriting precision within  $\pm 0.3$  millimeters and a writing speed of approximately 200 mm/min, positioning the system as a viable solution for educational, research, and assistive applications."

The findings of the initial tests carried out by the researchers are promising, as their system could produce realistic hand-written lines, which closely mirrored printed versions of AI-generated handwriting. In the future, this promising system could be fabricated on a larger scale and commercialized, potentially helping to make handwriting robotics more accessible to a broader range of consumers.
